

Task 3 – Activity B – Example Student Response (Distinction level)

Evaluation

Effectiveness of assets and content

ToKa Fitness wanted a website that offers personal training sessions and advice on fitness training and healthy living to its customers and requested that the following functional requirements.

ToKa Fitness key performance indicators for the proposed solution were:

- has free access with some accessibility to services
- accessibility features for customers with sight loss
- link to 'social media' features
- ability to view workout.

The owner wanted to develop a digital system that:

- provided information and advice about fitness training and healthy living to help customers improve their own health and fitness
- provided access to digital content to support customers with their training and healthy lifestyle
- encouraged existing customers who have access to digital devices to use more of the services provided by ToKa Fitness.

The prototype developed for ToKa Fitness uses a wide range of assets and content that enhance both functionality and user engagement. Embedded fitness videos provide clear demonstrations of exercises, while blogs and curated external links offer relevant advice on fitness training and healthy living.

Customisable tools, such as the eating plan and exercise logging features, further improve the user experience. For fitness tracking, the system allows users to log activity duration and compare it against personal goals. Reports generated from this data display daily and cumulative results, using colour-coded outputs to help users monitor progress. This design feature reinforces motivation.

The interface incorporates visual assets that align with ToKa Fitness's brand and objective of projecting a professional image. External content, such as videos and blog links, was checked for reliability and compliance with intellectual property and licensing requirements. This ensures that the solution reflects industry best practice and builds user trust in the platform.

When selecting assets and content for the prototype, I considered a range of options but deliberately rejected some. For example, I decided not to use stock fitness images from free, unverified sources because the quality was inconsistent and the copyright status was unclear, which could have created legal issues. Instead, I used licensed or verified free-to-use media to ensure compliance with intellectual property law.

How well the solution meets the requirements

I believe that the prototype developed meets ToKa Fitness and their customers' needs, and the majority of the customer acceptance criteria for the proposed system conditions have been met.

The website is suitable for the target customer group and complies with age restrictions and guidelines clear advice will be given to reduce health issues or injuries and complies with the industry's legal and ethical requirements. The customer area is secured and accessed via password and payment made in a secure platform. This complies with legal requirements. The privacy and security of customer data is important each member will have access to their area via secure login. This will ensure that ToKa Fitness is perceived as a reputable company and encourage existing customers who have access to digital devices to use more of the services provided by ToKa Fitness. Hopefully to also encourage new customers to use the website and services.

The website can be accessed via mobile devices and a computer and compatibility across different devices Android and iOS, as requested providing the customer with further options and flexibility of use especially accessibility the features for customers with sight loss.

Customers were able to access the system as a full customer with payment or free with limited access to the resources. The payment service offered a secure environment for these transactions complied with the legal requirements.

During the testing process, it was identified that further types of exercise needed to be added to the list, to allow the customer to provide an accurate record of their exercise. The exercise minutes and the type of exercise were calculated by the system to produce the fitness output, and this was compared to the customers' goal, and a difference was displayed.

Output	Goal output data	Difference
30 min	30 min	0

Each customer's fitness training plan allows the customer to meet their identified goal.

Providing links to the fitness training video and healthy living and eating video was another key requirement of the system. This provided access to digital content to support customers with their training and healthy lifestyle and information and advice about fitness training and healthy living to help customers improve their own health and fitness.

I believe that the majority of the functional and non-functional requirements of the system and legal requirements were met as the website provides customised information and advice about fitness training and healthy living to help customers improve their own health and fitness. Overall the website performed well the system was responsive, and user navigation worked well. Accessibility features for users with sight loss also available.

However, there were some elements that I was not able to fix after testing. There was a video that wasn't displaying correctly and not everyone was receiving the sign up email. I did not have enough time to make those work.

My proposed solution provides ToKa Fitness with a professional and easy to use system that promotes their business and encourage customers to use it.

On accessing the website the user lands on the website's homepage. The user can access the website under two different profile categories: a visitor, a registered user. The homepage contains a side navigation bar that allows easy access to different sections of the website. As a visitor the user can access the following sections of the website.

KPI	Evidence from project
Free access with some accessibility to services	Users can access the site as either free or full members. Free users have limited access; on-screen guidance helps them upgrade.
Accessibility features for customers with sight loss	Text-resize functionality included; contrast and layout optimised for visibility. CSS modified for better device compatibility.
Link to social media features	Site includes links to Instagram, Twitter and health blogs. Users can follow external verified links.
Ability to view workout	Fitness videos are embedded (e.g. YouTube), and accessible from within the platform. Links are verified and copyright compliant.
Information and advice about	Homepage, blog, embedded videos and

fitness training and healthy living	external links provide health and fitness content. Verified sources used.
Access to digital content to support training and healthy lifestyle	Includes videos, blog, food tracking tools, and personalised feedback.
Encourage existing customers with digital devices to use more services	Full and free access options promote flexible use; testers praised layout, navigation and usability.
Secure login and data privacy	Password-protected access; secure payment fields; secure login area mentioned.
Mobile and desktop compatibility	website tested on mobile and desktop. CSS changes made to ensure consistent layout.

Further development

One of the improvements identified during the testing process was the need to expand the list of exercise types. Several testers mentioned that common activities they regularly do, such as cycling or swimming, weren't available in the dropdown menu. This limited how accurately they could log their workouts. To address this, I would add a wider range of exercises and possibly include a free text option or integration with an exercise database. This would give users more flexibility and make the data outputs more useful.

Another suggestion from testers was to include clearer visual feedback when values updated on screen. For example, when a user adds food to their diary, the nutrition values do update, but the change isn't obvious. I would improve this by adding a short animation or colour highlight so users know the data has changed. This would improve the experience for new users who aren't yet familiar with how the system works.

There was also some frustration from users who wanted to link their fitness trackers, like Fitbits or smartwatches, to the site. Although this wasn't part of the original spec, it's something that could be developed further to improve accuracy and save users' time. Integrating with external APIs would allow automatic data input for steps, heart rate, and calories burned, making the reports more meaningful.

Finally, some users mentioned that while accessibility features like text resizing were available, they were hard to find. I would make these settings more visible on the homepage or include them as part of a first-time setup guide. This would help users with visual impairments and improve usability across all devices.

Task 3 – Activity B – Commentary

The student has produced a detailed and well-structured evaluation that clearly considers both the quality of the assets selected and the extent to which the prototype meets the needs of the client and its users. The content chosen is appropriate in tone and purpose, with thoughtful consideration of its suitability for a health-focused audience. The student demonstrates awareness of how sensitive topics such as weight management could affect users, showing a reflective and ethical approach to review.

Effectiveness of assets and content

The evaluation provides a comprehensive review of the assets and content within the prototype. A wide range of multimedia features, such as videos, blogs and eating plans, are justified as appropriate to the system's purpose. Validity and reliability are considered through checks on copyright and intellectual property, and legal and ethical aspects are acknowledged through secure login, payments and accessibility for sight loss.

To improve, the work could:

- explain more clearly why certain assets and content were rejected, and by strengthening the justification for those that were included
- extend the consideration of reliability by addressing bias, corroboration across sources, and the distinction between primary and secondary information
- broaden the ethical evaluation
- provide a stronger link between chosen assets and the measurable effect on user engagement and outcomes

Evaluation of the digital solution

The evaluation gives a comprehensive account of how the prototype meets functional and non-functional requirements. Secure login, payments, reports and multi-device compatibility are evidenced, and tester feedback is used to demonstrate that user acceptance criteria have been met. A KPI table is included, showing alignment between the system and the client's needs.

To improve, the work could:

- analyse KPI evidence more critically, comparing outcomes against measurable indicators rather than describing them

- evaluate non-functional requirements in greater depth, particularly scalability and long-term performance
- integrate tester feedback more directly with the acceptance criteria to demonstrate clear links between evidence and evaluation
- identify areas of partial fulfilment more explicitly to strengthen critical judgement

Further development

The evaluation includes a comprehensive rationale for future development, with suggestions that are supported by tester feedback, including expanding the exercise list, improving visibility of accessibility options, and considering fitness tracker integration. These points are relevant and practical, and they address gaps identified during testing.

To improve, the evaluation could:

- justify why these particular improvements were prioritised over alternative options
- show how each proposal would contribute to ToKa Fitness's business objectives and align with industry trends
- provide more detail on technical feasibility, particularly in relation to API integration and accessibility features
- demonstrate how further development would enhance both functional and non-functional aspects of the solution.
